

REPORT OF 1967 SURVEY OF SEDIMENT BASINS BELOW STREAM GAGE SITES
1, 2, and 3 ON THE H. J. ANDREWS EXPERIMENTAL FOREST

By Ross Mersereau

The 1967 survey report includes measurement notes from (1) measurement of sediment from watersheds 1 and 2, in July 1967, (2) the initial survey of the watershed 3 basin, in August 1966, after its remodeling in April 1966, and (3) the measurement of the watershed 3 basin in August 1967.

Treatment this year consisted of the burning of the slash in watershed 1, in October 1966, followed by cleaning of the creek bed throughout the winter.

On watershed 3, two winters have passed since the slide of December 1964. It has been four years since logging and eight years since road construction.

On watershed 1, it has been one year since completion of logging, and almost one year since the watershed was burned.

Measurements

Elevation measurements were consistent with those used in previous years. At watershed 3, the elevation of the auxiliary spike was found to be lower by .004 foot in August of 1967 than it had been in August of 1966, possibly caused by settling of the dam. This distance was taken into consideration during calculation of the "average bottom elevation."

Calculations

Sediment accumulation was determined by the procedures outlined in 1959 by Sturges.

"Line of sight" figures in Table 1 were computed so as to accommodate "line of site" errors, as was done in the 1966 report.

The .004 foot difference in elevation of the watershed 3 auxiliary spike created an error which would increase the "average bottom elevation;" therefore, this figure was subtracted from the 1967 "average bottom elevation" before the "change of average bottom elevation" was computed.

Because the watershed 2 accumulation was computed as a minus number, it was assumed that no change in bottom elevation took place. Therefore, ratios formed between sediment accumulations in the watershed 2 basin and those in watersheds 1 and 3 were considered meaningless; and no ratios were computed on Table 2.

Discussion

Throughout the winter of 1966-1967, visual observation indicated that large amounts of sediment were being deposited in the watershed 1 basin. These observations were borne out by measurement of the basin in 1967.

The average accumulation in the watershed 1 sediment basin of the ten years from 1957 through 1966 is .89 cubic feet per acre. This year the average accumulation was approximately 15 times greater. Considering the 1966-1967 treatment on watershed 1, we can ask the question: Should we attribute the increase in bedload volume in the watershed 1 sediment basin to the slash burning of watershed 1 in October 1966?

It is known that a number of slides occurred in the banks along the watershed 1 stream channel in January 1965. Because little of this slide material has appeared in the sediment basin before this year, it might be assumed that naturally occurring and/or logging deposited debris has obstructed its movement downstream. The burning of slash on the watershed was quite effective in removing the debris from the stream channel. Only those logs that might possibly have moved down the channel during high water were removed during the cleaning of the creek bed. Little if any overland movement of water has been noted in watershed 1 either before or since slash burning took place. Also, no slides of any consequence have taken place since the slash was burned. Therefore, it seems safe to assume (1) the greater part of the increase in bedload volume was derived from slide material which was already in the channel and (2) this side material was released by the removal of debris by slash burning.
